ABSTRACT

This is a report submission for the fourth project of «Computational physics» at the Institute of Physics, University of Oslo, autumn 2016.

For a 2×2-grid of consisting of spin values ± 1, it is straightforward to verify that the partition-function is given by

$$Z(\beta) = 12 + 2\left(e^{-8J\beta} + e^{8J\beta}\right)$$

and thus the n-momentums of energy E and magnetization M are given by

$$\langle E^n \rangle(\beta) = \frac{2}{Z}\left(8^n e^{-8J\beta} + (-8)^n e^{8J\beta}\right), \quad \langle M^n \rangle(\beta) = \frac{1}{Z}\left(4^n e^{8J\beta} + 4(2)^n + 4(-2)^n + (-4)^n e^{8J\beta}\right)$$

respectively. Use these, it is straight forward to compute the heat capacity at constant volume and magnetic susceptibility since these are proportional to the variance of E and M. They are

$$C_V = \frac{1}{kT^2}\sigma_E^2 = \frac{2^6}{kT^2}\left(\frac{2}{Z}\left(e^{-8J\beta} + e^{8J\beta}\right) - \frac{2^2}{Z^2}\left(e^{-8J\beta} - e^{8J\beta}\right)^2\right)$$

$$\chi = \frac{1}{kT}\sigma_M^2 = \frac{16}{ZkT}\left(2e^{-8J\beta} + 2 - (0)^2\right) = \frac{2^5}{ZkT}\left(1 + e^{-8j\beta}\right)$$

It remains to obtain the expressions for expected energy and mean magnitude of magnetization and expectation they are obtained from the momentum of the associated quantities:

$$\langle E \rangle(\beta) = \frac{2^4}{Z}\left(e^{-8J\beta} - e^{8J\beta}\right) \qquad \text{and} \qquad \langle |M| \rangle(J\beta) = \frac{2^3}{Z}\left(2 + e^{-8J\beta}\right).$$
